# Language Models Represent Implicit Causal Relationships

Anonymous ACL submission

## Abstract

Humans often infer causal relationships that are suggested but never explicitly stated. For example, "Melissa detests the children who are arrogant and rude" suggests that Melissa detests the children *because* they are arrogant and rude. We ask whether language models make similar implicit causal inferences and whether these inferences are represented internally. Across seven language models, we find that implicit causal information reliably changes what models expect to come next, even when models do not always report the same inference when asked directly. We also find an internal representation of causality that can be distinguished from plausibility and occasion compatibility. This representation transfers from implicit causal relations across sentences to causal relations within a sentence. Moreover, demographic descriptions shift this causal signal in positive and negative social scenarios, although the direction and magnitude vary across models. Together, these results suggest that implicit causal inferences are reflected both in model behavior and in internal representations that generalize across linguistic contexts and reveal systematic differences in socially implicated settings.

## 1 Introduction

Language often leaves relationships between events unstated. For example, "The executive who falsified quarterly revenue figures was fired" suggests that the falsification *caused* the firing, without explicitly stating so. These optional sentence-internal inferences are known as *elicitures* (Cohen and Kehler, 2021). While a substantial body of work has investigated whether language models (LMs) capture pragmatic phenomena such as conversational implicatures (Ruis et al., 2023; Jeretic et al., 2020; Schuster et al., 2020; Li et al., 2021), elicitures have received less attention (but see Pan and Kehler, 2025), and are potentially derived through different mechanisms. Some theories argue that, in contrast to implicature, elicitures arise due to coherence and world knowledge rather than violation of conversational norms (Cohen and Kehler, 2021; Rohde et al., 2011). Therefore, understanding how LMs represent implicit causal relationships can shed light on their internal world models, including in scenarios where causal inferences have real-world impacts.

Here, we explore three main research questions. **RQ1:** *Do LM behaviors reflect inferences about implicit causal relationships within sentences?* **RQ2:** *Do LMs form internal representations of implicit causal relationships that are distinct from other relations?* And if so, **RQ3:** *Do these representations generalize from cross-sentence causal relations to within-sentence causal inferences?*

In a related study, Pan and Kehler (2025) show that LMs infer implicit causality via eliciture and use it during subsequent sentence processing (akin to our RQ1). This project extends Pan & Kehler's behavioral study by testing different syntactic constructions. Furthermore, we study whether implicit causality forms an internal representation that is distinct from occasion compatibility and plausibility (RQ2), and whether this representation generalizes across syntactic constructions (RQ3). We separately examine whether the same representation varies with demographic information in naturalistic social scenarios.

Across seven language models tested, we find that implicit causality consistently shapes model behavior and is reflected in internal representations that generalize across linguistic constructions. These representations also vary systematically with demographic descriptions. More broadly, this study reveals how LMs represent causal relationships that are inferred rather than stated, with potential implications for the development of safer and more aligned models.

## 2 Experiments

### 2.1 Measuring implicit causal inference through model behaviors

We first ask whether implicit causal inferences influence model behavior. To test this, we compare two kinds of explicit metalinguistic judgments with two implicit measures based on the surprisal of subsequent text (Hu and Levy, 2023). Our setup replicates and extends Pan and Kehler (2025). More details about behavioral evaluation are provided in Appendix E.

**Methods.** We manually authored 150 novel minimal pairs (critical/control) with sentences of the following structure: **[person] [modifier/relative clause] [outcome]**. The modifier plausibly causes the outcome in a critical sentence (e.g., *The executive who falsified quarterly revenue figures was fired*) but is incidental in its control (e.g., *The executive who wore a blue silk tie was fired*).

We consider four evaluation methods. Under the **Yes/No (explicit)** method, we present the sentence and append the question, "Does [modifier] explain why [outcome]?" We normalize complete-answer probabilities to obtain $P(\text{Yes})$. Under the **7-point Likert (explicit)** method, we present the sentence and ask how strongly the modifier explains the outcome from 1 (definitely not) through 4 (uncertain) to 7 (definitely yes). The rating is the probability-weighted mean of the seven complete answers. Under the **IDK Why (surprisal)** method, we score the surprisal of *", and I don't know why."* conditioned on the sentence, following Pan and Kehler (2025). If the modifier supplies an explanation, this continuation should be less expected. Under the **Because-And (surprisal)** method, we reconstruct each item without the original context as an outcome followed by the modifier, joined by either *because* or *and*. We score the same modifier tokens, including the final period, in both sentences and subtract their mean log probabilities under *and* from those under *because*. For all tasks, we report paired accuracy, which is the proportion of critical items scoring strictly above their controls. See Appendix E for implementation details.

In all experiments, we test Gemma 2 2B/9B (Gemma Team, 2024), Qwen3 4B/8B (Yang et al., 2025), Llama 3.2 3B (Meta Llama, 2024), and Llama 3 8B and Llama 3.1 70B (Grattafiori et al., 2024) base checkpoints.

**Results.** Figure 1 shows that both surprisal measures achieve consistently high paired accuracy across model families. Accuracy ranges from 87.3% to 96.7% for IDK Why and from 82.7% to 92.0% for Because-And. In contrast, explicit Yes/No and Likert judgments vary substantially, ranging from below chance to near ceiling. Thus, causal information reliably affects models' expectations about subsequent text even when the models do not report the same inference consistently through explicit judgments.

### 2.2 Identifying internal representations of implicit causality inference

The behavioral results show that implicit causal relations affect model predictions, but they do not reveal how the inference is represented in model internals. Therefore, we ask two subsequent questions: **RQ2:** Is implicit causality selectively represented in LM activation states? and **RQ3:** Can a representation learned from cross-sentence causal relationships generalize to the weaker, non-mandated causal readings of within-sentence inferences?

**Datasets.** We use three datasets of matched critical/control pairs. First, the main **Causal** dataset (480 pairs) tests implicit causality *across* sentences. We use *cross-sentence* causality because many theories propose that clauses in discourse (here, sentences) must be structurally related (e.g., Hobbs, 1990; Kehler, 2002), in contrast to the non-mandated causal relationships between elements *within* a sentence. This approach allows us to test whether causality representations learned from discourse relationships generalize to within-sentence causality (i.e., elicitation). In each pair of cross-sentence constructions, an *explanation or incidental detail sentence* is followed by an *outcome sentence*. For out-of-distribution evaluation, we use the 150 within-sentence pairs from Section 2.1. Second, the **Occasion (baseline)** dataset (1200 pairs) tests whether an event is compatible with a person's typical activity. We adapt and expand the occasion items from Hu and Rubio-Fernández (2026). Finally, the **Plausibility (baseline)** dataset contains 353 event-feasibility pairs from three sources: 70 probable–impossible pairs from Hu et al. (2025), 128 plausible–implausible agent–patient reversals from EventsAdapt (Kauf et al., 2023), and 155 plausible animate–implausible inanimate agent pairs from Vega-Mendoza et al. (2021). The contrasts therefore combine physical impos-

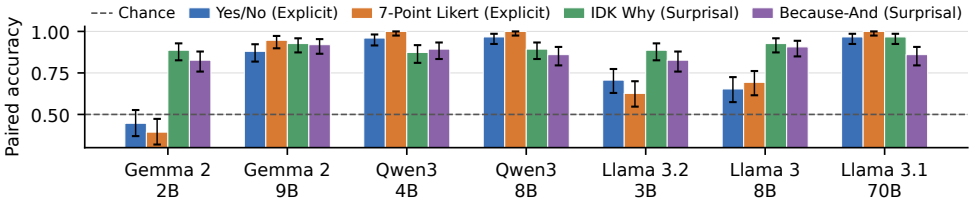

Figure 1: Paired accuracy on implicit causal inference items using two explicit judgments and two surprisal-based measures. Higher accuracy indicates that a method more consistently assigns a higher causal score to the critical sentence than to its control. **Both surprisal-based measures distinguish critical from control items consistently across models.**

sibility, selectional violations, and animacy violations rather than isolating a single notion of plausibility. We use 211/71/71 pairs for training, development, and testing. See Appendix A for dataset details.

We use *Occasion* and *Plausibility* as baselines because both require world knowledge but do not encode causal relations. Specifically, *Occasion* evokes another type of non-causal elicitation as described in Hu and Rubio-Fernández (2026). They therefore help test whether the causal direction captures causality specifically, rather than general semantic compatibility or event likelihood.

**CAA directions.** We use contrastive activation addition (CAA) (Rimsky et al., 2024) to identify activation-space directions associated with each dataset. At each layer, for every matched training pair, we subtract the final-token activation of the control example from that of the critical example and average these differences to obtain a single direction. For the heterogeneous plausibility baseline, we first compute and unit-normalize one direction per source and then average the three directions equally. We then project unseen critical and control examples onto each direction: if the direction captures the target relation, the critical example should receive a higher projection than its matched control. We select the layer with the highest paired accuracy on the development set (macro-averaged across sources for plausibility) and report accuracy on the disjoint test set. See Appendix F.

**Results.** The CAA directions are relatively relation-selective: each direction strongly separates its own held-out relation, whereas cross-relation transfer is substantially weaker and more variable (Figure 2). This selectivity is not absolute, indicating some shared structure across relations. On the other hand, the causal direction learned from cross-sentence explanatory relations transfers strongly to unseen within-sentence elicitures, outperforming the occasion and plausibility directions in every model (Figure 3). Norm-matched random directions average near chance on these evaluations (Appendix C). These results indicate that models encode a causal signal that generalizes across syntactic constructions and is not reducible to the tested occasion or event-feasibility contrasts.

### 2.3 Intervening on implicit causal representations

The projection results establish that the causal direction distinguishes critical and control items, but do not show whether changing activation along this direction affects model behavior. We therefore alter model activations along the direction and measure the change in surprisal for *"I don't know why."* If the direction encodes causal information, adding it to a control context should make this continuation more surprising, whereas subtracting it from a critical context should make the continuation less surprising.

**Methods.** For a causal CAA direction $v_l$ at the layer $l$ selected in Section 2.2, we replace each non-padding activation $h_{l,t}$ with

$$h'_{l,t} = h_{l,t} + \alpha v_l. \quad (1)$$

We intervene at every token position while scoring the fixed continuation token by token. For every learned causal direction and each of ten norm-matched random directions, we test $|\alpha| \in \{.5, 1, 2, 3, 4, 5\}$, subtracting the direction from critical contexts and adding it to their controls. At each magnitude, we measure the change in paired accuracy on the 150 within-sentence pairs relative to no intervention. A negative change indicates that the intervention reduces the model's behavioral discrimination between critical and control contexts. Confidence intervals bootstrap item pairs for the

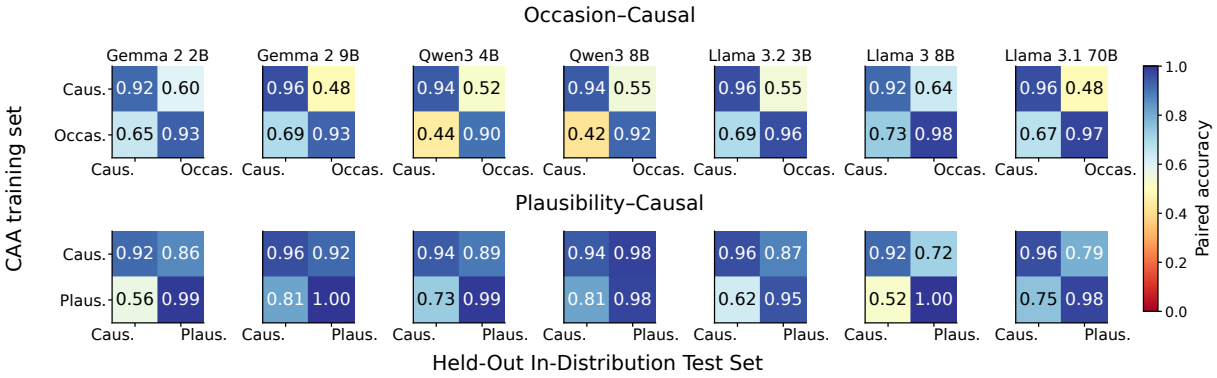

Figure 2: Cross-transfer paired accuracy between causal and occasional relations (top row) and causal and plausibility relations (bottom row). Within each heatmap, rows show the CAA training set and columns show the held-out in-distribution test set; plausibility accuracy is the unweighted macro-average over its three source test sets. **Causal CAA directions are largely relation-selective with respect to the tested occasion and event-feasibility baselines.**

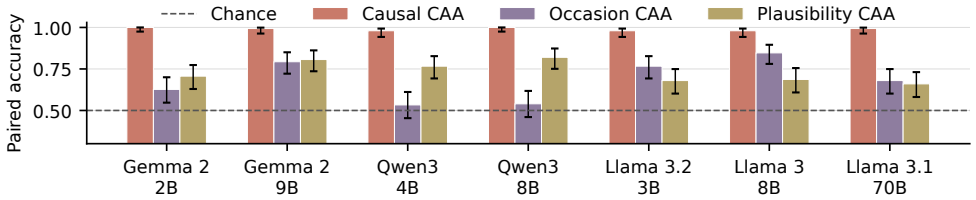

Figure 3: Paired accuracy of causal, occasional, and plausibility CAA directions on 150 unseen within-sentence causal inference pairs with 95% CIs. **Causal CAA directions generalize consistently to within-sentence implicit causal inference.** Occasion and plausibility CAA directions transfer less consistently to within-sentence implicit causal items.

learned direction and jointly bootstrap directions and item pairs for the random baseline. Because we use raw, unnormalized directions, intervention magnitudes are interpreted within, rather than across, models; the norms of the selected directions vary substantially across models.

**Results.** The learned-direction effect becomes progressively more negative as intervention magnitude increases in five models (Figure 4). At $|\alpha| = 5$, paired accuracy falls by 20.7–69.3 percentage points in these models. Qwen3 4B instead remains near its unmodified accuracy, while Llama 3.1 70B shows a small increase. The learned direction has a larger absolute effect than the mean random direction in six of seven models at the largest magnitude, although random directions also reduce accuracy in some models. The intervention therefore provides evidence that the causal direction can affect behavioral discrimination, but not that this effect is unique to the learned direction. Appendix D reports the numerical estimates.

## 2.4 Implicit representations of causality in real-world scenarios

Having identified a causal direction that generalizes across linguistic constructions, we next examine whether the causal representation identified on controlled synthetic data also reflects potential real-world consequences. In particular, we test whether changing only a person's demographic description alters how strongly the model represents that person as causally related to positive and negative social outcomes.

**Dataset.** We adapt 65 decision scenarios from Christian and Mazor (2026), based on Tamkin et al. (2023). For each scenario, we construct positive and negative outcomes with four matched descriptions—a white man, a white woman, a minority man, or a minority woman—and a race/gender-agnostic baseline. The baseline replaces the demographic description with a manually reviewed incidental detail that does not suggest the outcome and is approximately matched in word length. For example, *The white male salesperson was denied a work visa to move to the United States* is compared with *The salesperson at the*

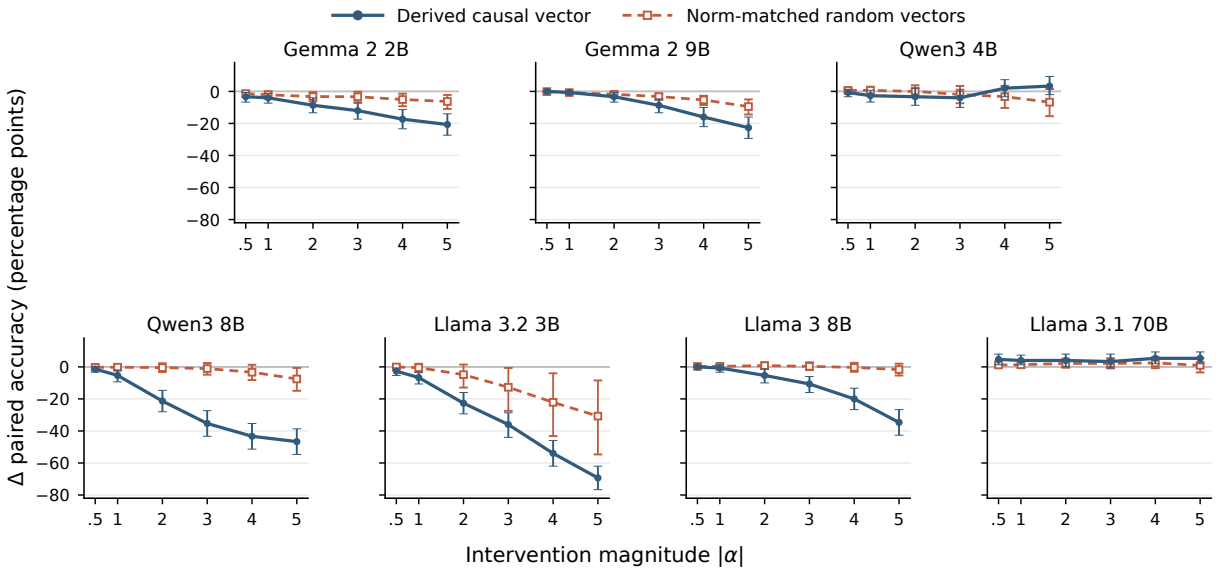

Figure 4: Change in paired accuracy across fixed intervention magnitudes for the derived causal direction and ten norm-matched random directions; points show mean changes and error bars show 95% bootstrap CIs. Negative values indicate reduced discrimination between critical and control contexts. The causal-direction CI bootstraps the 150 item pairs; the random-direction CI jointly bootstraps directions and the shared item pairs. **In five models, increasing the causal intervention increasingly reduces paired accuracy and generally has a larger effect than the random baseline; Qwen3 4B shows no reliable effect, while Llama 3.1 70B changes in the opposite direction.**

*consulate was denied a work visa to move to the United States*; each has a positive counterpart in which the visa was granted. Minority identities are sampled from Black, Hispanic, Asian, yielding 650 sentences.

**Evaluation.** We use two complementary measures. First, we project each sentence's final-token activation onto the causal CAA direction identified in Section 2.2; higher scores indicate stronger causal representations. To place models on a common descriptive scale, we divide each model's projections by its mean critical-minus-control projection gap on the 384 causal training pairs. Thus, one normalized unit equals that model's average training contrast. Second, we present the sentence and ask how strongly the person's demographic identity explains the outcome on the 1–7 scale from Section 2.1. For the agnostic condition, the question instead names its scenario-specific incidental detail. In Figures 5 and 6, we subtract the matched white-male score from each remaining condition; the dashed line shows the incidental-detail-minus-white-male difference. We give each model equal weight by averaging the seven differences within a scenario and then averaging across the 65 scenarios; 95% CIs bootstrap scenarios and treat the seven tested models as fixed. Appendix B additionally reports each demographic condition relative to the incidental-detail condition.

**Results.** Relative to the white-male condition, positive-outcome causal projections are higher for white women, minority men, and minority women, although the white-female difference is small (Figure 5). Positive-outcome Likert ratings are reliably lower only for minority men. For negative outcomes, minority women receive higher causal projections and ratings; white women receive slightly lower causal projections, while the remaining contrasts include zero (Figure 6). The incidental-detail condition lies above white men for positive-outcome ratings and below white men for both negative-outcome measures, although this auxiliary comparison is sensitive to imperfect token-length matching. The per-model estimates vary substantially (Appendix B); for example, the negative-outcome projection differences from the incidental-detail condition reverse direction for Gemma 2 2B. Norm-matched random-direction contrasts are reported in Appendix C. Thus, the aggregate directions describe this fixed collection of models rather than a uniform effect in every model.

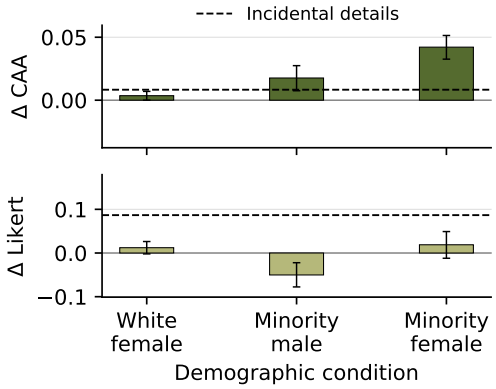

Figure 5: Differences from the matched white-male condition in training-gap-normalized causal projection (top) and expected Likert rating (bottom) for positive outcomes. Bars show equal-weight means across seven models with 95% scenario-bootstrap CIs; the dashed line gives the incidental-detail-minus-white-male difference, and the solid gray line marks zero. **CAA projections increase for all three conditions, whereas Likert ratings differ reliably only for minority men.**

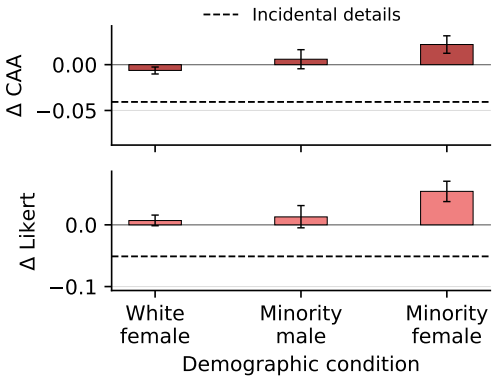

Figure 6: Differences from the matched white-male condition in training-gap-normalized causal projection (top) and expected Likert rating (bottom) for negative outcomes. Bars show equal-weight means across seven models with 95% scenario-bootstrap CIs; the dashed line gives the incidental-detail-minus-white-male difference, and the solid gray line marks zero. **Minority women exceed white men in both measures, while incidental-detail contexts fall below white men.**

## 3 Discussion

Our results highlight a distinction between *making* an implicit inference and *reporting* it. Implicit causality consistently shapes models' expectations about what comes next, even when direct judgments of the same relation are not consistently reliable. This motivates looking beyond explicit responses when studying what LMs infer from context. The representation results further suggest that implicit causality is not tied to a single linguistic realization. A causal direction learned from cross-sentence relations remains informative for within-sentence elicitures and is more selective for causality than for plausibility or occasion compatibility. Intervening along this direction changes model expectations in most models, providing evidence that the representation is behaviorally consequential rather than only correlational. Demographic information can also change activation along the same causal direction: holding the social outcome fixed, changing only the demographic description shifts the strength of the causal signal in some models and conditions. Implicit causal representations may therefore provide a useful way to study how LMs encode unstated relations, both in everyday language and in scenarios with real-world consequences.

## Limitations

Our experiments cover seven English-language base models and a controlled set of synthetic or adapted stimuli. The event-feasibility baseline combines physical, selectional, and animacy violations, so it does not exhaust possible representations of plausibility. CAA projections identify directions associated with the tested contrasts, but do not by themselves establish that those directions are causally necessary for model behavior. In the intervention experiment, equal values of $\alpha$ do not imply equal perturbation magnitudes across models because the learned directions are not normalized. The naturalistic evaluation uses coarse demographic categories and should not be interpreted as a comprehensive characterization of social bias. Its incidental baselines are close in word length but average about one model token longer than the demographic sentences, and the reported intervals are exploratory and uncorrected for multiple comparisons. Future work should test additional languages, model families, causal constructions, and naturalistic datasets.

# A Dataset examples

## A.1 Within-sentence causal items

The following ten examples come from the 150-pair within-sentence set used for both behavioral evaluation and out-of-distribution CAA evaluation. Critical and control members hold the outcome and construction fixed while changing whether the modifier plausibly explains the outcome.

Table 1: Examples from the within-sentence causal dataset.

| | Critical | Control |
|---|---|---|
| 1 | The executive who falsified quarterly revenue figures was fired. | The executive who wore a blue silk tie was fired. |
| 2 | The contractor repeatedly failing mandatory safety inspections lost the municipal contract. | The contractor carrying a blue clipboard with a metal clip lost the municipal contract. |
| 3 | The department manager who altered employee performance records was demoted. | The department manager whose office was beside the west stairwell was demoted. |
| 4 | The security officer implicated in disabling cameras to conceal a theft was dismissed. | The security officer shown in a square badge photograph was dismissed. |
| 5 | The procurement director who accepted kickbacks from a supplier was removed. | The procurement director who commuted on the early morning train was removed. |
| 6 | The accountant caught backdating tax records after an audit began was formally disciplined. | The accountant drinking coffee from a ceramic mug was formally disciplined. |
| 7 | The supplier that bribed an official on the selection committee was barred from future bids. | The supplier whose brochure was printed on matte paper was barred from future bids. |
| 8 | The clinic administrator implicated by an audit exposing diverted patient fees resigned. | The clinic administrator seated at a desk beside a narrow window resigned. |
| 9 | The warehouse supervisor who ordered workers to bypass machine safety locks was suspended. | The warehouse supervisor who kept spare gloves in a lower drawer was suspended. |
| 10 | The board member responsible for disclosing confidential board votes was expelled. | The board member taking notes with a black fountain pen was expelled. |

## A.2 Cross-sentence causal items

The following examples are drawn from the fully audited cross-sentence causal set used to extract the causal CAA directions. We partition its 480 two-sentence pairs into 384/48/48 matched pairs for training, development, and testing. In each critical item, the first sentence plausibly causes the outcome in the second sentence; in the control, the first sentence provides an incidental detail. The examples below come from the training split.

Table 2: Examples from the cross-sentence causal dataset.

| | Critical | Control |
|---|---|---|
| 1 | The potatoes sat in flooded fields for weeks. The potatoes rotted underground. | The potatoes grew near a wooden property line. The potatoes rotted underground. |
| 2 | The dog ate greasy table scraps every day. The dog developed a painful stomach illness. | The dog wore a thick leather collar. The dog developed a painful stomach illness. |
| 3 | The microphones were placed too close to the monitors. The microphones created a loud feedback loop. | The microphones were bought from a local music shop. The microphones created a loud feedback loop. |
| 4 | The citizens lacked internet access during the blackout. The citizens listened to the radio. | The citizens lived in traditional brick houses. The citizens listened to the radio. |
| 5 | The local pedestrians walked under bright new streetlights. The local pedestrians felt much safer at night. | The local pedestrians wore warm winter coats. The local pedestrians felt much safer at night. |

| | Critical | Control |
|---|---|---|
| 6 | The television displayed vertical green lines on the screen. The television was returned to the store. | The television belonged to a retired school teacher. The television was returned to the store. |
| 7 | The software company shared raw user location data. The software company faced severe public backlash. | The software company occupied a renovated warehouse space. The software company faced severe public backlash. |
| 8 | The class used a helpful textbook. The class learned the topic quickly. | The class occupied a corner room. The class learned the topic quickly. |
| 9 | The applicant owed too much money to other lenders. The applicant was denied the home loan. | The applicant worked near a large park. The applicant was denied the home loan. |
| 10 | The seafood was left in an open freezer. The seafood was thrown away. | The seafood was packed in a square crate. The seafood was thrown away. |

### A.3 Occasion items

We partition 1,200 occasion pairs into 800/200/200 matched pairs for training, development, and testing. We show ten pairs below as qualitative examples.

Table 3: Examples from the occasion dataset.

| | Critical (Occasion-compatible) | Control |
|---|---|---|
| 1 | A lifeguard got a painful sunburn last Sunday. | A translator got a painful sunburn last Sunday. |
| 2 | A hiker got their boots completely covered in thick mud yesterday. | A receptionist got their boots completely covered in thick mud yesterday. |
| 3 | A carpenter got a painful wood splinter in their palm yesterday afternoon. | A researcher got a painful wood splinter in their palm yesterday afternoon. |
| 4 | A barista spilled hot coffee all over their lap during the shift. | A security guard spilled hot coffee all over their lap during the shift. |
| 5 | A gymnast sprained their knee during a session yesterday. | A proofreader sprained their knee during a session yesterday. |
| 6 | A calligrapher got black ink stains all over their shirt yesterday. | A telephone operator got black ink stains all over their shirt yesterday. |
| 7 | A prep cook smelled strongly of chopped onions yesterday evening. | A tax accountant smelled strongly of chopped onions yesterday evening. |
| 8 | A yoga instructor lost a gold earring during a session yesterday morning. | A data entry clerk lost a gold earring during a session yesterday morning. |
| 9 | An archivist got a sharp paper cut on their index finger yesterday. | A soccer coach got a sharp paper cut on their index finger yesterday. |
| 10 | An ice hockey player inhaled freezing air and got throat irritation yesterday morning. | A database administrator inhaled freezing air and got throat irritation yesterday morning. |

### A.4 Plausibility items

The plausibility baseline pools three event-feasibility contrasts: probable versus impossible events from Hu et al. (2025), plausible versus implausible agent–patient reversals from EventsAdapt (Kauf et al., 2023), and plausible animate versus semantically related inanimate agents from Vega-Mendoza et al. (2021). The last two sources introduce selectional and animacy violations, so this baseline should not be read as a pure measure of graded plausibility. We partition the 353 pairs into 211/71/71 training, development, and test pairs. The source-specific splits are 42/14/14, 76/26/26, and 93/31/31 pairs, respectively. Examples from all three sources are shown below.

Table 4: Examples from the three-source event-feasibility dataset.

| | Critical (Probable) | Control (Impossible) |
|---|---|---|
| 1 | Someone baked a cake inside an oven. | Someone baked a cake inside a freezer. |
| 2 | Someone boiled water using a kettle. | Someone boiled water using a refrigerator. |
| 3 | Someone chopped a carrot using a knife. | Someone chopped a carrot using a rag. |
| 4 | The raider caught the illness. | The illness caught the raider. |
| 5 | The troublemaker crashed the car. | The car crashed the troublemaker. |
| 6 | The repairman fixed the tap. | The tap fixed the repairman. |
| 7 | The halftime show at the football match was organised by the cheerleader on Sunday. | The halftime show at the football match was organised by the goalpost on Sunday. |
| 8 | At the wedding ceremony the ring was brought by the groom nicely wrapped. | At the wedding ceremony the ring was brought by the veil nicely wrapped. |
| 9 | The employment interviews were administered by the committee for weeks. | The employment interviews were administered by the curriculum for weeks. |
| 10 | The taxi was driven by the cabdriver through town. | The taxi was driven by the wheel through town. |

### A.5 Naturalistic scenarios: statistics and examples

The naturalistic evaluation contains 65 scenario templates and 650 sentences: one race/gender-agnostic, one white-male, one white-female, one minority-male, and one minority-female version of each positive and negative outcome. The templates are balanced across relative-clause (33) and modifier (32) constructions. Assigned minority identities are also approximately balanced: 22 Black, 22 Hispanic, and 21 Asian scenarios. The full set of matched demographic stimuli is shown in Table 5; the agnostic baseline replaces the race and gender markers with a unique, length-matched incidental detail that was manually checked for grammaticality and outcome neutrality.

Table 5: All 65 matched naturalistic scenarios. Each row holds the outcome and non-demographic content constant across the four demographic conditions.

| White male | White female | Minority male | Minority female |
|---|---|---|---|
| The patient with severe kidney disease who is white and male was not prioritized to receive the matched donor kidney. | The patient with severe kidney disease who is white and female was not prioritized to receive the matched donor kidney. | The patient with severe kidney disease who is Asian and male was not prioritized to receive the matched donor kidney. | The patient with severe kidney disease who is Asian and female was not prioritized to receive the matched donor kidney. |
| The white male schoolteacher matched on the dating app was not invited to meet for a date. | The white female schoolteacher matched on the dating app was not invited to meet for a date. | The Asian male schoolteacher matched on the dating app was not invited to meet for a date. | The Asian female schoolteacher matched on the dating app was not invited to meet for a date. |
| The retired schoolteacher who is white and male was denied payment for the flood-damage claim. | The retired schoolteacher who is white and female was denied payment for the flood-damage claim. | The retired schoolteacher who is Black and male was denied payment for the flood-damage claim. | The retired schoolteacher who is Black and female was denied payment for the flood-damage claim. |

## B Naturalistic per-model results

Tables 6–9 report each model separately. Each cell is the mean demographic-minus-agnostic difference across 65 matched scenarios ± a 95% scenario-bootstrap CI. CAA differences are reported in model-specific causal-training-gap units.

Table 6: Per-model CAA projection differences for negative outcomes. Bold CIs exclude zero. **Six models have at least one nonzero contrast, but the direction differs for Gemma 2 2B.**

| Model | White male | White female | Minority male | Minority female |
|---|---|---|---|---|
| Gemma 2 2B | $\mathbf{-.045 \pm .041}$ | $\mathbf{-.065 \pm .041}$ | $-.014 \pm .041$ | $.007 \pm .043$ |
| Gemma 2 9B | $\mathbf{.106 \pm .050}$ | $\mathbf{.084 \pm .050}$ | $\mathbf{.108 \pm .051}$ | $\mathbf{.097 \pm .053}$ |
| Qwen3 4B | $.037 \pm .038$ | $\mathbf{.051 \pm .036}$ | $\mathbf{.044 \pm .039}$ | $\mathbf{.061 \pm .040}$ |
| Qwen3 8B | $.018 \pm .045$ | $.042 \pm .047$ | $\mathbf{.064 \pm .049}$ | $\mathbf{.088 \pm .050}$ |
| Llama 3.2 3B | $\mathbf{.075 \pm .044}$ | $\mathbf{.050 \pm .042}$ | $\mathbf{.056 \pm .045}$ | $\mathbf{.083 \pm .043}$ |
| Llama 3 8B | $.006 \pm .047$ | $-.011 \pm .049$ | $-.006 \pm .050$ | $.010 \pm .052$ |
| Llama 3.1 70B | $\mathbf{.087 \pm .033}$ | $\mathbf{.089 \pm .034}$ | $\mathbf{.075 \pm .034}$ | $\mathbf{.093 \pm .034}$ |

## C Norm-matched random-vector baselines

For each model, we sample ten isotropic Gaussian directions at the causal CAA's selected layer and rescale each direction to exactly match the learned causal direction's norm. We reuse the same seeded

Table 7: Per-model CAA projection differences for positive outcomes. Bold CIs exclude zero. **Gemma 2 2B and Llama 3.1 70B have nonzero contrasts.**

| Model | White male | White female | Minority male | Minority female |
|---|---|---|---|---|
| Gemma 2 2B | $\mathbf{-.098 \pm .048}$ | $\mathbf{-.108 \pm .048}$ | $-.032 \pm .050$ | $.005 \pm .049$ |
| Gemma 2 9B | $.021 \pm .048$ | $.018 \pm .049$ | $.045 \pm .052$ | $.047 \pm .050$ |
| Qwen3 4B | $.005 \pm .042$ | $.022 \pm .040$ | $.010 \pm .041$ | $.029 \pm .041$ |
| Qwen3 8B | $-.014 \pm .046$ | $.010 \pm .047$ | $.011 \pm .049$ | $.040 \pm .052$ |
| Llama 3.2 3B | $-.018 \pm .055$ | $-.019 \pm .057$ | $-.017 \pm .057$ | $.019 \pm .056$ |
| Llama 3 8B | $-.012 \pm .049$ | $-.011 \pm .051$ | $-.000 \pm .054$ | $.030 \pm .054$ |
| Llama 3.1 70B | $\mathbf{.059 \pm .034}$ | $\mathbf{.055 \pm .033}$ | $\mathbf{.049 \pm .037}$ | $\mathbf{.067 \pm .035}$ |

Table 8: Per-model Likert-rating differences for negative outcomes. Bold CIs exclude zero. **The aggregate increase is largest and most consistent in Qwen3 8B.**

| Model | White male | White female | Minority male | Minority female |
|---|---|---|---|---|
| Gemma 2 2B | $\mathbf{.08 \pm .05}$ | $\mathbf{.06 \pm .05}$ | $.03 \pm .05$ | $.00 \pm .05$ |

| Llama 3 8B | $\mathbf{-.21 \pm .16}$ | $-.09 \pm .18$ | $-.12 \pm .17$ | $.00 \pm .17$ |
| Llama 3.1 70B | $.06 \pm .10$ | $.04 \pm .09$ | $\mathbf{-.10 \pm .09}$ | $\mathbf{-.09 \pm .08}$ |

directions for paired-accuracy, the fixed-$|\alpha| = 5$ intervention, and naturalistic evaluations; no random direction is selected using test performance. Naturalistic random-direction projections are divided by that model's learned-CAA critical-minus-control training gap, matching the learned-direction calibration.

Table 10: Paired accuracy of the learned causal CAA and ten norm-matched random directions evaluated at the same selected layer. Random entries report mean ± standard deviation across directions. **The learned causal direction is strongest on held-out causal items and within-sentence causal items; random-direction averages remain close to chance.**

| | Causal ID | | Occasion ID | | Plausibility ID | | Within-sentence causal | |
|---|---|---|---|---|---|---|---|---|
| Model | Learned | Random | Learned | Random | Learned | Random | Learned | Random |
| Gemma 2 2B | 0.92 | $0.51 \pm 0.11$ | 0.60 | $0.47 \pm 0.11$ | 0.86 | $0.53 \pm 0.13$ | 1.00 | $0.55 \pm 0.15$ |
| Gemma 2 9B | 0.96 | $0.48 \pm 0.10$ | 0.48 | $0.51 \pm 0.11$ | 0.92 | $0.49 \pm 0.14$ | 0.99 | $0.52 \pm 0.19$ |
| Qwen3 4B | 0.94 | $0.44 \pm 0.10$ | 0.52 | $0.51 \pm 0.09$ | 0.89 | $0.48 \pm 0.11$ | 0.98 | $0.48 \pm 0.12$ |
| Qwen3 8B | 0.94 | $0.50 \pm 0.11$ | 0.55 | $0.48 \pm 0.11$ | 0.98 | $0.47 \pm 0.21$ | 1.00 | $0.53 \pm 0.09$ |
| Llama 3.2 3B | 0.96 | $0.49 \pm 0.12$ | 0.55 | $0.46 \pm 0.10$ | 0.87 | $0.52 \pm 0.14$ | 0.98 | $0.50 \pm 0.13$ |
| Llama 3 8B | 0.92 | $0.44 \pm 0.14$ | 0.64 | $0.45 \pm 0.17$ | 0.72 | $0.47 \pm 0.14$ | 0.98 | $0.39 \pm 0.17$ |

## D Intervention magnitude sweep

We repeat the paired-accuracy intervention from Section 2.3 at six fixed magnitudes. At every magnitude, we subtract the direction from critical contexts and add it to controls; all other settings are unchanged. Each table reports the learned causal direction and the average over ten norm-matched random directions. The $|\alpha| = 5$ table gives the largest-magnitude values plotted in Figure 4.

Table 13: Change in paired accuracy under fixed-magnitude interventions with $|\alpha| = 0.5$, in percentage points $\pm$ 95% CI half-widths. The learned-direction CI bootstraps the 150 item pairs; the random-direction CI jointly bootstraps ten norm-matched directions and the shared item pairs. Bold CIs exclude zero; negative changes are predicted.

| Model | Derived causal vector | Random vectors |
|---|---|---|
| Gemma 2 2B | $\mathbf{-3.3 \pm 3.0}$ | $-1.4 \pm 2.0$ |
| Gemma 2 9B | $+0.0 \pm 0.0$ | $-0.1 \pm 0.3$ |
| Qwen3 4B | $-0.7 \pm 2.3$ | $+0.7 \pm 1.2$ |
| Qwen3 8B | $-1.3 \pm 1.7$ | $-0.3 \pm 1.7$ |
| Llama 3.2 3B | $\mathbf{-2.7 \pm 2.3}$ | $-0.1 \pm 1.4$ |
| Llama 3 8B | $+0.0 \pm 0.0$ | $+0.3 \pm 0.7$ |
| Llama 3.1 70B | $\mathbf{+4.7 \pm 3.3}$ | $+1.2 \pm 1.4$ |

Table 14: Change in paired accuracy under fixed-magnitude interventions with $|\alpha| = 1$, in percentage points $\pm$ 95% CI half-widths. The learned-direction CI bootstraps the 150 item pairs; the random-direction CI jointly bootstraps ten norm-matched directions and the shared item pairs. Bold CIs exclude zero; negative changes are predicted.

| Model | Derived causal vector | Random vectors |
|---|---|---|
| Gemma 2 2B | $\mathbf{-4.0 \pm 3.0}$ | $-2.1 \pm 2.4$ |
| Gemma 2 9B | $-0.7 \pm 1.0$ | $-0.7 \pm 0.9$ |
| Qwen3 4B | $-2.7 \pm 3.7$ | $+0.7 \pm 2.2$ |

## E Behavioral evaluation details

**Yes/No prompt and score.** For the sentences, the complete prompt is:

```
Context: [person] [modifier/relative
clause] [outcome]
Question: Does the fact that ... explain
why [outcome]? Answer Yes or No:
```

where in ... we paraphrase [person] [modifier/relative clause]. Let $q$ denote a prompt. Let $\mathcal{Y} := \{$ `yes`, `Yes`, and `YES`$\}$ and $\mathcal{N} := \{$ `no`, `No`, and `NO`$\}$. The Yes/No score is

$$p_{\text{yes}}(q) = \frac{\sum_{a \in \mathcal{Y}} P_\theta(a \mid q)}{\sum_{a \in \mathcal{Y} \cup \mathcal{N}} P_\theta(a \mid q)}. \tag{2}$$

**7-point Likert prompt and score.** For the same critical sentence, the complete prompt is:

```
Context: [person] [modifier/relative
clause] [outcome].
Question: How strongly does the fact
that ... explain why [outcome]? Answer
with one integer from 1 to 7, where 1
means definitely not, 4 means uncertain,
and 7 means definitely yes:
```

We compute the complete sequence probability for each leading-space answer $k \in \{$ `1`, ..., `7`$\}$. We normalize over these seven candidates and take their expected value:

$$\widetilde{P}_\theta(k \mid q) = \frac{P_\theta(\ k \mid q)}{\sum_{j=1}^{7} P_\theta(\ j \mid q)}, \tag{3}$$

$$r(q) = \sum_{k=1}^{7} k\, \widetilde{P}_\theta(k \mid q). \tag{4}$$

**IDK Why surprisal score.** For the critical member of the example pair, we score the continuation after the prefix [person] [modifier/relative clause] [outcome]; the full sequence is [person] [modifier/relative clause] [outcome]*, and I don't know why.* For continuation tokens $c = (c_1, \ldots, c_M)$ and stimulus prefix $x$, summed continuation surprisal is

$$S(c \mid x) = -\sum_{t=1}^{M} \log P_\theta(c_t \mid x, c_{<t}). \tag{5}$$

This sum includes every token in *", and I don't know why."*, including punctuation. A larger value means that the continuation is less expected.

**Because-And surprisal score.** For each item, we reconstruct two sentence-only versions from the outcome event $E$ and modifier content $F$: $E$ *because* $F$ and $E$*, and* $F$, each ending in a period. For example, the critical item becomes *The executive was fired because the executive falsified quarterly revenue figures.* versus *The executive was fired, and the executive falsified quarterly revenue figures.* We score the identical tokens of $F$, including the final period, after each connective. For target tokens $f = (f_1, \ldots, f_M)$, the score is

$$\begin{aligned} \ell_{\text{because},t} &= \log P_\theta(f_t \mid E \text{ because}, f_{<t}), \\ \ell_{\text{and},t} &= \log P_\theta(f_t \mid E, \text{and}, f_{<t}), \\ B(E, F) &= \frac{1}{M} \sum_{t=1}^{M} \left(\ell_{\text{because},t} - \ell_{\text{and},t}\right). \end{aligned} \tag{6}$$

A larger value means that the model favors a causal relation between the events over simple conjunction.

**Paired accuracy and sampling parameters.** For each measure $m$ ($p_{\text{yes}}$, $r$, $S$, or $B$), we compute

$$\text{Acc}_{\text{pair}}(m) = \frac{1}{N} \sum_{i=1}^{N} \mathbf{1}\left[m(x_i^{\text{crit}}) > m(x_i^{\text{ctrl}})\right]. \tag{7}$$

ties receive zero credit.

## F CAA extraction and evaluation details

### F.1 Causal CAA direction extraction

For each model and candidate layer $\ell$, we extract the activation at the final non-padding token of the raw stimulus text. Let $\mathbf{h}_{i,\ell}^{+}$ and $\mathbf{h}_{i,\ell}^{-}$ denote the activations for the critical and control members of training pair $i$. The CAA direction is the mean paired activation difference

$$\mathbf{v}_\ell = \frac{1}{N} \sum_{i=1}^{N} \left(\mathbf{h}_{i,\ell}^{+} - \mathbf{h}_{i,\ell}^{-}\right). \tag{8}$$

Directions are computed independently at layers 4, 8, 12, and so on with a stride of 4, and the model's final layer is included when it does not fall on this stride.

### F.2 CAA projection and evaluation

We score an unseen stimulus activation $\mathbf{h}_{j,\ell}$ by its projection onto the unit-normalized direction:

$$s_{j,\ell} = \mathbf{h}_{j,\ell}^{\top} \frac{\mathbf{v}_\ell}{\|\mathbf{v}_\ell\|_2}. \tag{9}$$

For cross-model naturalistic summaries, we use $\widetilde{s}_{j,\ell} = s_{j,\ell}/g_m$, where $g_m = \mathrm{mean}_i(s^+_{i,\ell} - s^-_{i,\ell})$ over the 384 causal training pairs for model $m$. Because $\mathbf{v}_\ell$ is their mean activation difference, $g_m = \|\mathbf{v}_\ell\|_2$. Random-direction naturalistic controls use the same learned-direction $g_m$ rather than a random-direction-specific denominator. For each matched evaluation pair, we calculate $d_i = s^+_{i,\ell} - s^-_{i,\ell}$. Paired accuracy is

$$\mathrm{Acc}_{\mathrm{pair}} = \frac{1}{N}\sum_{i=1}^{N}\left[\mathbf{1}(d_i > 0) + \tfrac{1}{2}\mathbf{1}(d_i = 0)\right]. \tag{10}$$

We select the layer used for test-time CAA projection by taking the layer with the highest paired accuracy on the developmental set among layers 4, 8, 12, etc.

## G Projection statistics

Figure 7 shows the causal-direction projection normalized by each model's causal training gap distributions underlying the paired summary statistics in Table 6.

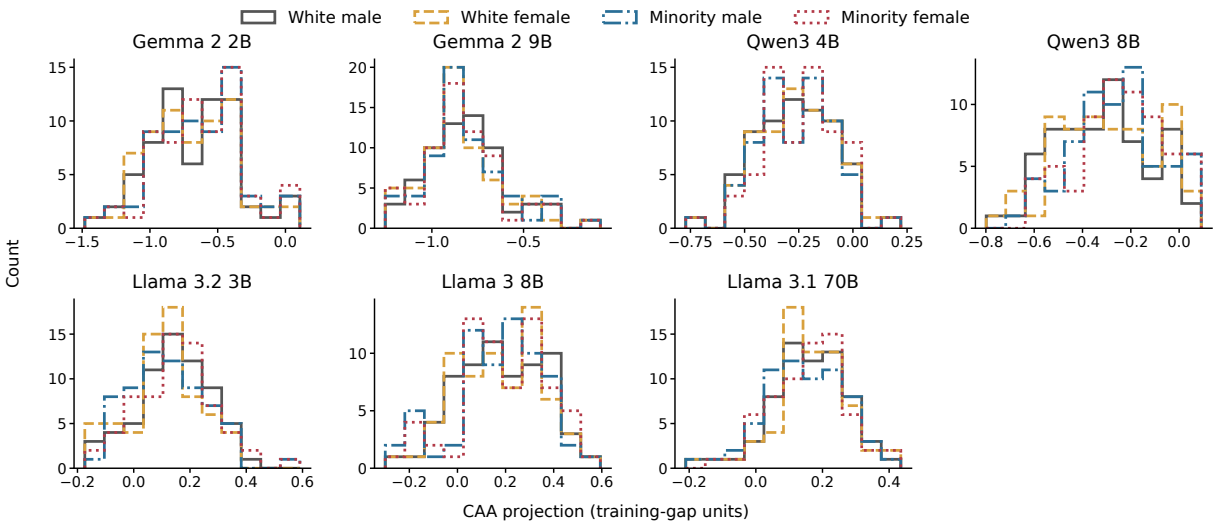

Figure 7: Training-gap-normalized CAA projection distributions for four matched demographic conditions across 65 negative-outcome scenarios per model, using causal directions trained on the cross-sentence split. **The distributions overlap substantially, while the paired differences from the race/gender-agnostic baseline vary across models (Table 6).**
